

CRICKET PLAYER PERFORMANCE TRACKING APPLICATION

A SALESFORCE PROJECT REPORT

Project Domain: Salesforce CRM / Cloud Application

Submitted as part of academic project work

Salesforce Developer Edition

1. OBJECTIVE

The main objective of the Cricket Player Performance Tracking Application is to create a centralized Salesforce application for storing, managing, and tracking cricket player performance data. The application helps users maintain player details, match statistics, batting and bowling records, and performance-related information in an organized way.

The system reduces manual record keeping and makes player information easier to access. Salesforce objects, tabs, relationships, roll-up summary fields, and flows are used to build the application.

2. USERNAME

A Salesforce Developer account provides a unique username for accessing the Salesforce environment. The username is created during registration and is used to log in to the Salesforce Developer Edition.

For this project, the developer username can be entered as the username created by the student during Salesforce account registration. The username should be kept secure and should not be shared publicly.

3. INTRODUCTION

Cricket involves a large amount of player performance information such as runs, matches, wickets, strike rate, economy rate, catches, and other statistics. Managing these records manually can become difficult when the number of players and matches increases.

The Cricket Player Performance Tracking Application uses Salesforce to provide a structured platform for maintaining player and performance information. Administrators can create player records, enter performance details, connect related records, and automate selected tasks using Salesforce Flow.

The application demonstrates how Salesforce can be customized for a sports-performance management use case.

4. PROJECT OVERVIEW

The application is designed around two important areas: player information and performance information. A Player object stores basic details such as Player Name, Team, Role, Age, and Contact information. A Performance object stores match-related statistics such as Runs, Wickets, Matches Played, Balls Faced, Overs Bowled, and Catches.

Relationships between objects allow performance records to be associated with the correct player. Roll-up summary fields can calculate totals such as total runs or total wickets. Flows can automate notifications or update related information when records are created or changed.

5. PROJECT CREATION

The project can be created using Salesforce Developer Edition. After signing in, the student can open Setup and use Object Manager to create the custom objects and fields required for the application.

Suggested custom objects are:

- Player – stores player master information.
- Performance – stores individual match or performance records.
- Team – stores team information if required.

Suggested Player fields include Player Name, Player ID, Role, Team, Age, Phone, Email, Total Runs, Total Wickets, and Matches Played.

Suggested Performance fields include Performance Name, Player, Match Date, Runs, Wickets, Balls Faced, Overs Bowled, Catches, and Match Result.

6. SALESFORCE DEVELOPER ACCOUNT CREATION

To create a Salesforce Developer account, the student visits the Salesforce Developer registration page and provides the required registration details such as name, email address, username, and password. After completing verification, the student can log in to the Developer Edition org.

Basic steps:

1. Open the Salesforce Developer registration page.
2. Enter the required personal and account details.
3. Create a unique Salesforce username.
4. Submit the registration form.
5. Verify the email if requested.
6. Log in to Salesforce Developer Edition.
7. Open Setup to begin application development.

The Developer Edition provides an environment for learning Salesforce configuration and development.

7. TABS

Tabs provide an easy way to access objects and application data from the Salesforce interface. Custom tabs can be created for the objects used in this project.

Recommended tabs:

- Players – displays player records.
- Performances – displays performance records.
- Teams – displays team records, if created.
- Reports – provides access to performance reports.
- Dashboards – displays summarized performance information.

Tabs make navigation simple and allow users to reach important application data quickly.

8. THE LIGHTNING APP

Salesforce Lightning App Builder and Lightning App configuration can be used to create a user-friendly application interface. A Lightning application can contain the required tabs and navigation items for the cricket performance system.

A suitable application name is “Cricket Player Performance Tracker”. The navigation menu can include Players, Performances, Teams, Reports, and Dashboards.

The Lightning interface allows users to view records, create new records, edit existing records, and access related information from a single application environment.

9. FILES AND RELATIONSHIPS

Salesforce Files can be used to attach or store supporting documents and media related to records. For example, a player profile image, performance document, or match-related file can be associated with a player or performance record.

Relationships connect records between objects. A Lookup Relationship provides a flexible connection between two objects, while a Master-Detail Relationship creates a stronger dependency between the detail record and its master record.

For this project, Performance can be related to Player so that every performance record belongs to a particular player. This relationship makes it possible to view a player's related performance history.

10. ROLL-UP SUMMARY

A Roll-Up Summary field is useful when the master record needs summarized information from related detail records. In this project, the Player object can contain roll-up summary fields based on Performance records when a suitable Master-Detail relationship is used.

Examples:

- Total Runs – SUM of Runs from Performance records.
- Total Wickets – SUM of Wickets.
- Total Catches – SUM of Catches.
- Matches Played – COUNT of related Performance records.

These fields provide quick performance totals on the Player record without manually calculating the values.

11. FLOWS

Salesforce Flow is used to automate business processes without requiring traditional programming for many common tasks. A Flow can be created to perform actions when a record is created or updated.

Example flow for this project:

1. Start when a Performance record is created.
2. Identify the related Player.
3. Read the performance details.
4. Update or process the required player information.
5. Send a notification when required.
6. Save the changes.

Flows can help reduce repetitive manual work and improve consistency in the application.

12. CONCLUSION

The Cricket Player Performance Tracking Application demonstrates how Salesforce can be used to build a practical sports management application. The project uses custom objects, fields, tabs, Lightning application features, relationships, roll-up summaries, Files, and Flows.

The application provides an organized method for storing player information and tracking cricket performance. It also demonstrates Salesforce automation and data-management capabilities. The project can be extended in the future with dashboards, advanced reports, additional performance metrics, mobile access, and more automation.

SAMPLE DATA STRUCTURE

Object	Important Fields	Purpose
Player	Player Name, Player ID, Role, Team, Age	Stores player details
Performance	Match Date, Runs, Wickets, Catches	Stores match performance
Team	Team Name, Coach, Captain	Stores team details

Note: Field names can be modified according to the actual Salesforce org configuration used during project implementation.
